Abstract— Numerous technologies have been deployed to assist and manage transportation over the years. But recent concerted efforts in academia and industry point to a paradigm shift in intelligent transportation systems. Vehicles will carry computing and communication platforms and will have enhanced sensing capabilities. They will enable new versatile systems that enhance transportation safety and efficiency and will provide infotainment. This paper surveys the state-of-the-art approaches, solutions, and technologies across a broad range of projects for vehicular communication systems.

Keywords- Communication; Vehicular Networks; Intelligent Transportation Systems

I. INTRODUCTION

The growing mobility of people and goods incurs high societal costs: traffic congestion, fatalities and injuries. In the past decade, numerous efforts sought to mitigate these problems and produced solutions we currently use, for example: Information on traffic and hazardous situations are broadcast via the FM radio band, interrupting temporarily the user-tuned reception; variable message signs, spaced a few kilometers apart or at strategic points (e.g., merging highways, tunnels, bridges) along freeways, warn drivers about changing conditions; electronic toll systems collect fees with reduced or almost no disruption of the traffic flow.

At the same time, vehicles have increasingly effective driver assistance and protection mechanisms: Various on-board controls and information sources allow the driver to customize her driving experience and remain up-to-date on the vehicle status; passive safety mechanisms protect the passengers and the vehicle against adverse driving conditions (e.g., anti-lock braking systems); navigation systems, compasses, rear and front parking radars and cameras, are the most common among autonomous sensor technologies that perceive the landscape, the road, and the vehicle location, and capture in real time the vehicle surroundings and traffic situation, to appropriately warn the driver and either avoid accidents or at least reduce their effects. Beyond these technologies, relying on heterogeneous technologies (e.g.

road-side cameras), more complex systems enable fleet management and the collection of traffic information.

Recent technological developments, notably in mobile computing, wireless communication, and remote sensing, are now pushing Intelligent Transportation Systems towards a major leap forward. Vehicles are already sophisticated computing systems, with several computers and sensors onboard, each dedicated to one part of the car operation. The new element is the addition of new wireless communication, computing and sensing capabilities. Interconnected vehicles not only collect information about themselves and their environment, but they also exchange this information in real time with other, nearby (in principle) vehicles.

To put it simply, radio communication based solutions can operate beyond the line-of-sight constraints of radar and vision solutions, and they can enable cooperative approaches. Vehicles and infrastructure cooperate to perceive potentially dangerous situations, in an extended space and time horizon. Appropriate *vehicular communication* (VC) architectures are necessary to create reliable and extended driving support systems for road safety and transportation efficiency.

This paper contributes a survey of VC systems, covering the developments of the past few years. We cover the state of the art; we distill the technical details from a wide range of research and development projects. Rather than an architectural view alone, we seek to capture concisely and quantitatively the most up-to-date understanding in industry and academia.

We first provide an overview of VC systems and their role in intelligent transportation systems, along with a summary of the related major activities to date (Section II). Then, we present on-board equipment in Section III, the VC wireless data link technologies in Section IV, the VC networking protocols in Section V, and the VC-enabled applications in Section VI. We conclude with discussion on the next steps in the evolution of VC systems.

Figure 1 Illustration of VC system functionality: Safety applications leverage on vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communication, to extend the driver's horizon and offer early detection of perilous situations and notify accordingly the driver. It is currently debated whether some automated control action should be taken in future systems, for example, to ensure the avoidance of a collision without the intervention of the driver.

II. OVERVIEW

Vehicles will be equipped with novel *computing*, *communication*, and *sensing* capabilities and *user interfaces*. These will support a spectrum of applications that enhance *transportation safety* and *efficiency*, but also provide new or integrate existing services for drivers and passengers. A significant role is envisioned for existing or upcoming wireless infrastructure (e.g. cellular), connectivity to the wire-line part of the Internet, and dedicated *road-side infrastructure units* (RSUs). User-portable devices are also expected to be wirelessly attached to the on-board equipment.

A key aspect of VC systems is to expand the time horizon of information relevant for driving safety and transportation efficiency, introduce new sources and improve its quality. The basis is a *collaborative approach*, with each vehicle and RSU contributing relevant information, illustrated in Figure 1: based on their own sensing and on information received from nearby peers and RSUs, vehicles can anticipate, detect, and avoid dangerous or unwanted situations. For example, timely notifications about lane changes, emergency braking, and unsafely approaching vehicles can be highly beneficial. The same is true for notifications about dangerous or heavy traffic conditions disseminated by RSUs, locally or within a larger region with the help of other vehicles.

Figure 2 Common Reference Architecture for Cooperative Vehicular Communication Systems, as agreed primarily among European projects.

The development of such VC systems and related technologies has been the subject of numerous projects around the globe, as well as for standardization working groups and industrial consortia. We summarize the large majority of such recent efforts in TABLE I, with projects having complementary but often similar objectives and approaches. The table summarizes the objectives of each project, consortium, or initiative, along with its duration and context.

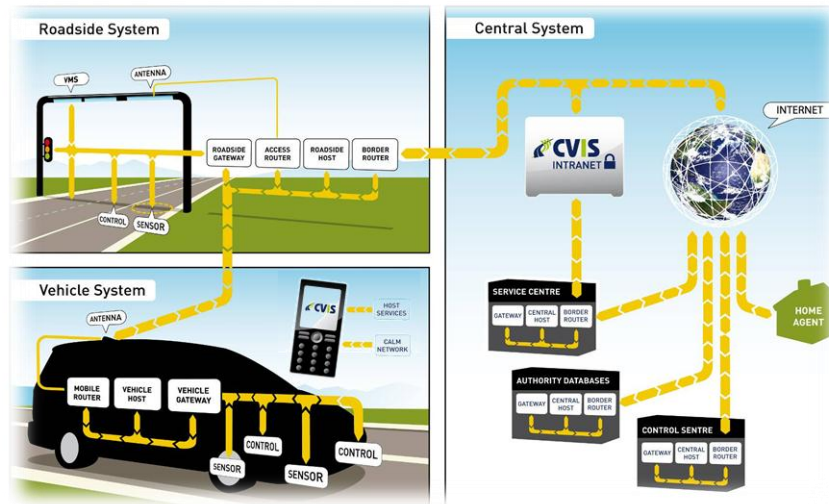

Figure 3 System Architectural View, as per the CVIS approach. Roadside and onboard equipment communicate; the roadside equipment provides access to information stored in a number of databases and servers related to the VC system, but also to the user's home equipment through mobile IPv6 connectivity.

TABLE I SUMMARY INFORMATION ON REPRESENTATIVE VC PROJECTS, CONSORTIA, AND WORKING GROUPS (*in alphabetical order*)

Project Name	Project Information		
	Period	External Funding	Brief description of objectives

<i>CAMP / VSC-2</i>	2005-2009	Department of Transportation USA	Cooperative Intersection Collision Avoidance System – Violations (CICAS-V); Emergency Electronic Brake Lights (EEBL); Vehicle Safety Communications–Applications (VSC-A):

This multitude of concerted efforts and approaches indicates the need for coordination. Co-operative system projects in Europe, notably those represented in the *COMeSafety* initiative, have converged on a common reference architecture, shown in Figure 2, with direct involvement from ETSI TC ITS and ISO TC204 WG16 (ITS Communications). It has therefore been adopted quite widely in Europe, and in several cases outside Europe. The architecture is described in [10] and a concise survey is given in [8].

Simply speaking, wireless transmission and medium access technologies adapted to the VC environment are the primary enabling technology. Conceptually, on top of them, networking technologies allow for data exchange among nearby and remote devices (vehicles, RSUs, and other servers). They, in turn, support the aforementioned range of applications, with the mediation of a range of facilities, that is, functionality that extracts data (mostly, location- and time-stamped) from the network operation and establishes sessions between two VC system entities when necessary. The basic system entity is an ITS Station, which can be composed of a Router and a Host or if can be a single-box implementation that covers all functions. One example is the top level architecture of the CVIS project shown in Figure 3.

III. ON-BOARD EQUIPMENT

The VC computing, communication, and sensing equipment and user interfaces will be, in most cases, new with respect to the current on-board equipment. In terms of sensing and user interface hardware and software, VC systems will leverage on the array of equipment vehicles currently carry; e.g., data concerning the vehicle operation, which are necessary for the VC operation, will be obtained via the corresponding or upgraded on-board interfaces. In general, this technology will not be developed from scratch but, as ongoing projects show, mature and well-understood components and their variants will be the basis. In the rest of this section, we outline the characteristics of the on-board equipment as it is currently developed and integrated.

VC computing platforms are to be dedicated to VC functionality. Recall that cars are already equipped with multiple processors and microcontrollers dedicated to tasks such fuel injection, braking, transmission, battery charging, etc; for easy reference, we term these *car processors and controllers*. The VC computing platform(s) will be functionally independent and responsible for running the V2V and V2I communication protocols and the supported applications.

The current approach is to use commercial, off-the-shelf computing technology with good performance and flexible interfaces. There are differences with existing desktop and laptop machines: *Car PCs* have relatively *hardened hardware* and *adapted packaging* so that operation is possible in a wider range of conditions and according to the VC constraints. In addition, *Car PCs* have the appropriate interface to the rest of the in-vehicle information system, which is essentially the *Control Area Network (CAN)* or other technologies (such as LIN, MOST or Flexray) that interconnect car processors and controllers [1].

Figure 4 illustrates one approach along these lines, as developed by the CVIS project. Rather than having one Car PC, there are two boxes: one performing all networking operations and acting as the interface to the car processors and sensors (termed the *Mobile Router*), and one doing all the computing for the VC applications and the user interface (termed the *Mobile Host*). The Mobile Router integrates a special-purpose card that integrates sensors and resolves, at the hardware level, time-critical tasks such as the real-time acquisition of location and time and synchronization. The use of two boxes appears in other projects too (e.g., the COM2REACT platform).

Sensing equipment is already installed on-board, thus a CAN gateway is present to obtain data from onboard sensors, typically: velocity, direction, temperature, airbag status, rear and front cameras, parking assistance radars, etc. At the same

time, *Global Navigation Satellite Systems (GNSS)* such as the *Global Positioning System (GPS)* can also be integrated, along with other advanced systems, such as collision warning or advanced cruise control radars.

The accuracy of location and time depends on the GPS receiver and its signal processing capabilities. For example, small-footprint receivers can achieve 10 to 15 nanosecond synchronization and localization errors of 6 to 30 meters. There are other GNSS solutions, such as the Russian counterpart of GPS that is compatible with the US-built GPS, and the upcoming European Galileo system (currently, with one operational satellite while the rest of the constellation is being deployed).

The COM2REACT project integrated a CAN gateway, a GPS, a camera and ultrasound transceivers. The CVIS project developed a special sensor card (mentioned above, as part of the Mobile Router PC). The card provides GPS data for accurate time and position, an inertial sensor package with gyroscope and accelerometers, and an interface to vehicle CAN-bus. The provided real-time processing and time stamping is important for the networking and application protocols described later in this paper. Similar efforts, in terms of extracting information safety-related sensory measurements from the in-vehicle system, are undertaken by SAFEPROBE, a subproject of SAFESPOT.

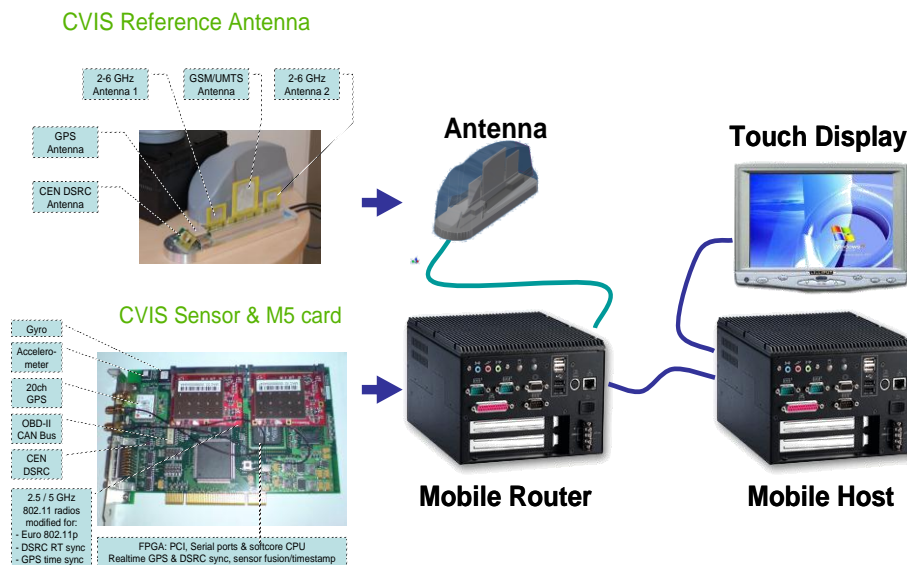

Figure 4 On-board Vehicular Communication (VC) system equipment (i) Computing platforms (Mobile router and Mobile Host), (ii) Communication equipment, with multiple wireless data links (e.g., 802.11p, cellular) and broadcast receivers (e.g., GPS), (iii) Sensors, and (iv) In-vehicle user interface.

Communication equipment comprises a set of technologies with different characteristics (bit rates, communication range, transmission power, frequency bands). Basically, there is *short-range ad hoc communication* to enable primarily V2V but also V2I communication, and *long-range infrastructure-based communication* primarily for V2I

purposes. Finally, there is the option of integrating additional long-range broadband transceivers, including broadcast receivers.

The basis of VC systems is a variant of the widely known Wi-Fi technology, termed the *IEEE 802.11p* protocol [3].

The corresponding transceivers provide for a wireless data link, discussed in Section IV, being the basis of the short-range ad hoc communication. Cellular data transceivers provide for the long-range communication: typically, *Global System for Mobile communications* (GSM) based *General Packet Radio Service* (GPRS) transceivers, as well as third

generation *Universal Mobile Telecommunications System* (UMTS) transceivers. Moreover, dedicated transceivers, e.g., for deployed toll collection systems - *Dedicated Short Range Communication* (DSRC) - can also be present.

TABLE II SUMMARY INFORMATION ON REPRESENTATIVE VC WIRELESS DATA LINKS

Indicative Wireless Data Link Characteristics	Technology			
	802.11p WAVE	Wi-Fi	Cellular	Infrared
<i>Bit rate</i>	3-27Mbps	6-54 Mbps	< 2Mbps	< 1 Mbps < 2 Mbps (CALM IR)
<i>Communication Range*</i>	< 1000 m	< 100 m	< 15 km	< 100 m
<i>Transmission Power for mobile (maximum)</i>	760 mW (US) 2 W EIRP (EU)	100 mW	2000 mW (GSM) 380 mW (UMTS)	12800 W/Sr pulse peak
<i>Channel Bandwidth</i>	10 MHz 20 MHz	1-40 MHz	25 MHz (GSM) 60 MHz (UMTS)	N/A (optical carrier)
<i>Allocated Spectrum</i>	75 MHz (US) 30 MHz (EU)	50 MHz @ 2.5 GHz 300 MHz @ 5 GHz	(Operator dependent)	N/A (optical carrier)
<i>Suitability for mobility</i>	High	Low	High	Medium
<i>Frequency band(s)</i>	5.86-5.92 GHz	2.4 GHz, 5.2 GHz	800 MHz, 900 MHz 1800 MHz 1900 MHz	835-1035 nm
<i>Standards</i>	IEEE, ISO, ETSI	IEEE	ETSI, 3GPP	ISO

*The communication range depends on parameters such as data rate, power, bandwidth, topography etc; values given in this table are estimates and may vary.

The frequency allocation for this communication equipment can differ from continent to continent and possibly from country to country. Regarding the newly introduced 802.11p, also known as the encompassing effort of the *Wireless Access in the Vehicular Environment* (WAVE) and the related IEEE 1609 working group activities, there are specific bands allocated for the V2V and V2I communication.

The CVIS platform (Figure 4) has GSM and UMTS interfaces, a dedicated DSRC transceiver, GSM/UMTS transceiver supporting all data modes, and short-range 802.11p radios that are synchronized with European DSRC Toll Collection systems. The 802.11 radios offer communication (in the European 5.9GHz band) along with the previous versions of the protocol, i.e., the IEEE 802.11 a/b/g, and an implementation of the IEEE 1609 stack and support for parallel protocol stacks (based on the CALM architecture). Similarly, SAFESPOT builds on the IEEE 802.11p radios and looks into possible integration of other technologies (cellular or infrared communication); COM2REACT used Wi-Fi 802.11b with GPRS.

IV. WIRELESS DATA LINK

As explained in Section II, vehicles are envisioned to carry multiple types of wireless transceivers, i.e., each vehicle will be able to communicate across more than one wireless data links. Each of them provides a *physical layer*, i.e., the implementation of methods to transmit and receive data (symbols representing bit sequences) across the airwaves, and a *medium access control layer*, i.e., protocols that regulate how collocated transceivers access (i.e., transmit and receive across) the wireless medium, in order to reduce the chance or avoid collisions (transmissions overlapping in frequency and/or time).

In TABLE II, we summarize indicative values for a set of characteristics of and information on the main wireless data links currently developed and integrated in automotive systems. Beyond operational characteristics (e.g., bit rate, range, bandwidth), we also point out which standards pertain to each technology. The interested readers are referred to the documentation of the corresponding standardization bodies for more information.

An important aspect, the medium access control latency, is not listed in the table, as it depends greatly on the implemented system and context. Infrastructure based communication may require delays in the order of seconds, including the association of a mobile transceiver with an infrastructure element, and the registration with the network

that grants access rights; this may be, for example, the case for Wi-Fi and cellular systems. Nonetheless, customized implementations of 802.11-based systems allow for very fast association with a Wi-Fi access point, while fast hand-over techniques allow cellular systems to service nodes moving fast from one base station to another. For transportation safety applications, low-latency communication with neighboring devices is critical; this favors direct V2V communication through a simple medium access control protocol.

The prominent wireless data link for VC is a variant of the IEEE 802.11 termed 802.11p. This specifies a physical and a medium access control protocol designed with the highly volatile vehicular environment in mind. The operation across multiple channels is specified in the IEEE 1609.4 standard. These two elements combined with a resource manager for the on-board equipment and specifications of addressing and networking services and security services are known collectively as the *WAVE* standard; for a recent tutorial, see [7].

V. NETWORKING PROTOCOLS

Beaconing is a simple mechanism, used in scores of other networks, to periodically transmit short messages, i.e., a one-hop or local broadcast. Beacons have a special role in VC systems: they provide the identity and rich information on the transmitting vehicle, e.g., location, heading, and other status information, with typical size in the order of 100 bytes. They are transmitted at high frequencies, e.g., 10 times per second, by each vehicle and in an uncoordinated manner. They are the backbone of the cooperative awareness and other transportation safety applications discussed in Section VI.

Beacons are transmitted across the 802.11p/WAVE data link and are typically handled as broadcast packets at the medium access control layer. Beaconing can also be event-driven local broadcasts, perhaps repeated for a protocol-specific period (e.g., a safety related warning triggered by an in-vehicle event). Safety-related beacons must arrive at neighbor nodes within a specific maximum delay and their reception should be possible with a minimum reliability, as per the application requirements.

At this point, VC implementations do not attempt reliable broadcast, but rather take very simple best-effort approaches that rely on redundant transmissions. Under highly congested settings, with one hundred vehicles within range, the reception reliability can be rather low, e.g., 60% of transmitted beacons; however, each vehicle transmits a beacon every ten milliseconds, thus within a fraction of second, even after several lost beacons, reception is possible.

Flooding is the natural extension of beaconing across multiple wireless hops. Packets specify a time to live, i.e., a

number of hops to be relayed across, or their type and content allow receivers to determine whether to re-broadcast them. Eventually, flooded packets are removed from the network after covering (approximately) the intended area. As it is the initial sender's information that is essential, the relaying nodes of packets flooded in a controlled manner do not need to modify them. This implies that their size as they propagate across the network would not increase. The same would be true if nodes performed some sort of aggregation, with relaying nodes 'adding' for example their measurement to an average or a maximum or a minimum of the values of nodes involved in the protocol execution.

GeoCast or Position Based Routing assumes that every node knows its geographical position, e.g. by GPS, and maintains a location table with the geographical positions of other nodes as soft state. Individual nodes can be addressed based on their geographical location, and a group of nodes can be designated as receivers within a geographical region. Such functionality, investigated also in the more abstract context of ad hoc networks, fits naturally into VC systems: (i) vehicles are already integrating navigation systems (e.g. GPS) and they are expected to be location aware, and (ii) many transportation safety and efficiency applications are location-specific. VC is, in fact, closer to GeoCast than to the usual Internet unicast [9].

The choice of a geographic region as a destination for a message is clearly independent of the size of the network, i.e., the number of the vehicles present. Individual vehicle addressing, which requires sufficiently accurate knowledge of the destination location, is expected to be a small fraction of the overall traffic. These two aspects clue that appropriate GeoCast protocols could remain efficient as the scale of the VC systems grows.

The basic components of GeoCast are (i) beaconing, for *discovery of neighbors* and their locations, (ii) a *location service*, which can be queried to provide the location of individual nodes, (iii) the *position based forwarding* towards a given destination (geographic location in general, which can be narrow or broad (region)).

The *maintenance of a neighborhood*, i.e., information on the set of other vehicles and roadside units within range, along with position and all other relevant information, can be done in various ways. For example, unreliable links can be disregarded (e.g., if a vehicle appears to move relatively fast with respect to a sender, or if the data link reports a high number of retries). Or neighbors that appear more 'relevant,' i.e., have the same heading (e.g., in the same highway flow).

The goal of the *location service* is to resolve the identity of a vehicle to its current position. This could be done with the help of facility that maintains locations of vehicles that need to be individually addressed. The instantiation of such a facility can be based on the infrastructure (which can be

reached across one or more wireless hops), or done in a peer to peer manner with the locations distributed across nodes. Access to such a facility or possibly to the sought vehicle can be done with a traditional query: a packet is flooded in a controlled manner, requesting the destination, with any authorized and knowledgeable node (RSU or vehicle) responding with the required location information. Location queries and responses are small-size packets, at most at the same size as beacons, at most in the order of 100 bytes.

Position-based forwarding relays each packet from its source to the destination location, based on individual decisions made at each relaying node based on knowledge about the neighborhood. The objective is to get the packet to approach

the destination at each relaying step: the source and each relay choose the next hop that is closest to the destination. This is the basic idea of a greedy forwarding, which under some circumstances can be ineffective: there may be no next hop closest to the destination and in that case a ‘gap avoidance’ algorithm invoked. Once the packet is in the destination region, nodes within the region broadcast locally the packet. As these are data packets, their payload can be in the order of several hundreds of bytes. Their control overhead, i.e., their headers, does not need to grow with the size of the network; they only need to specify both the destination, used by all relaying nodes, and the next hop

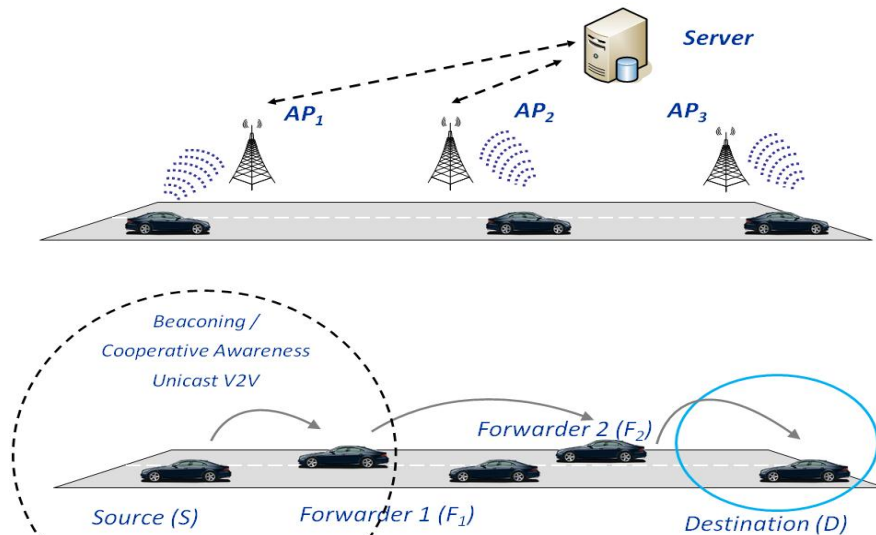

Figure 5 Illustration of networking protocols for VC systems: (Top) Internet connectivity via roadside and other infrastructure, and vehicle to infrastructure communication, (Bottom) Vehicle to vehicle communication, for communication with neighboring devices (directly reachable vehicles and roadside infrastructure), as well as devices across multiple hops and at a remote geographical region.

The *Car-2-Car Communication Consortium (C2C-CC)* has invested a significant effort into the specification of car-to-car communication mechanisms suitable for safety applications, including geo-networking (or GeoCast). *GeoNet* is a European Union funded project that aims at ensuring convergence between IPv6 and proprietary geo-networking protocols, particularly C2C-CC’s geo-networking.

Connectivity with the Internet is in general required, and it can be achieved with the vehicle establishing sessions with Wi-Fi access point when in range and down- or up-loading possibly large volumes of data within a short period of time, notably during the ‘contact’ with – i.e., the period of being in range of – the access point. Or, of course, Internet connectivity can be achieved via the cellular GSM/GPRS or UTM systems, which already have very high coverage. Internet connectivity can be infrequent a support for various VC-specific transactions and tasks. But it could also be established independently of transportation related issues, for infotainment.

Ongoing projects such as CVIS are developing a communication architecture that relies on the maintenance of a constant access to the Internet over IPv6. GeoNet ensures convergence between geo-networking and IPv6. The goal of GeoNet is to implement and formally test a geo-networking mechanism as a stand-alone software module that can be incorporated into Cooperative Systems. GeoNet is very active in standardization and will integrate its module into CVIS platform so that future projects for Cooperative Systems can maintain their focus on architecture design, application development and field trials.

VI. APPLICATIONS

VC systems will enable applications in three primary directions: (i) *transportation safety*, (ii) *transportation efficiency*, and (iii) *user services delivered to the vehicle*. The first two categories are the main two drivers for the development of the new systems. The third category leverages on the newly coined and existing systems, in many

cases it can naturally blend into the VC and ITS contexts, and can act as market driving force.

Projects, standardization bodies, and consortia around the globe have been working on the design and development of applications for VC systems. Long lists of applications were initially compiled, projecting onto the future technologies but drawing on existing transportation requirements and functionality, looking into how VCs can undertake and enhance support for those. The vast majority of applications fall largely in the above-mentioned three categories: (i) the driver is assisted, in order to enhance transportation safety, (ii) data, most often region-specific, about the transportation system and traffic conditions are made available to drivers, to enhance transportation efficiency, and (iii) services

enhance the users' (passengers and drivers) comfort and ability to perform personal and business transactions while in the vehicle.

In TABLE III, we provide a representative list of applications from these three categories. Names do not exactly match those used in each and every project, but rather they are closely compatible with those used by many projects and consortia (e.g., C2C-CC, VSC-A), standardization efforts (e.g., ETSI, IEEE), as well as those broadly used (e.g., SAFESPOT, CVIS, COM2REACT, SEVECOM).

TABLE III VC-ENABLED APPLICATIONS AND THEIR CHARACTERISTICS

	Application Name	Application Information				
		Communication	Messaging type	Message period	Latency	Other requirements
1	Emergency Electronic Brake Lights	Ad hoc V2V	Event-triggered, Time-limited Broadcast	100 ms	100 ms	Range: 300 m, High priority
2	Slow Vehicle Warning	Ad hoc V2V	Periodic Permanent Broadcast	500 ms	100 ms	High priority
3	Intersection Collision Warning	Ad hoc, Infrastructure V2V, V2I	Periodic Permanent Broadcast	100 ms	100 ms	Accurate positioning on a digital map, High priority
4	Hazardous Location Warning	Ad hoc, Infrastructure I2V, V2V	Event-triggered Time-limited GeoCast	100 ms	100 ms	High priority
5	Traffic Signal Violation Warning	Ad hoc, Infrastructure I2V	Event-triggered Time-limited Broadcast	100 ms	100 ms	Range: 250 m, High priority
6	Pre-Crash Sensing	Ad hoc V2V	Periodic Broadcast Unicast	100 ms	50 ms	Range: 50 m High/Mid priority for beaconing/unicast
7	Lane Change Warning	Ad hoc V2V	Periodic Broadcast	100 ms	100 ms	Relative positioning accuracy: < 2 m Range: 150 m
8	Cooperative Forward Collision Warning	Ad hoc V2V	Periodic, Event-triggered Broadcast, Unicast	100 ms	100 ms	Relative positioning accuracy: < 1 m Range: 150 m
9	Intersection Management	Infrastructure, Ad hoc V2I, V2V	Periodic Broadcast Unicast	1000 ms	500 ms	Positioning accuracy: < 5m
10	Limited Access and Detour Warning	Infrastructure, I2V Other broadcast network	Periodic Broadcast	100 ms	500 ms	Mid/low priority
11	Cooperative Adaptive Cruise Control	Ad hoc V2V	Unicast Broadcast	500 ms	100 m	Mid priority
12	Electronic Toll Collect	Infrastructure, Ad hoc V2I, Cellular	Periodic Broadcast Unicast	1000 ms	200 ms	CEN DSRC
13	Remote Diagnosis / JIT Repair Warning	Infrastructure, Ad hoc V2I, V2V, Cellular	Unicast Broadcast Event-triggered	N/A	500 ms	Internet access Service availability
14	Media Download	Infrastructure; Cellular, Other broadcast network	Unicast, Broadcast On-demand	N/A	500 ms	Internet access Digital rights management

16	Ecological Drive Assistance	Infrastructure, Ad hoc V2I, V2V, Cellular	Unicast, Broadcast On-demand	1000 ms	500 ms	Internet access Service availability

We provide a list of five pieces of information for each application: (i) *Communication*, which determines the

wireless data link needed, with ad hoc and infrastructure based referring to Section IV; (ii) *Messaging type*, which specifies whether the transmission is periodic, event-triggered, limited over a short period, etc., (iii) *Message period*, applicable to periodic messaging applications, (iv) *Critical latency*, the maximum delay the application requires from the underlying protocol stack to handle and transmit the message, and (iv) *Other requirements*, such as the priority at the medium access control layer, the accuracy of positioning, maximum recommended communication range, etc.

Among hundreds of use cases, we chose here a subset of applications to illustrate differing requirements. We do not propose values for each application, but rather reflect the content of various technical reports. We refer the interested reader to the deliverables of all the above mentioned projects and the technical reports issued by the consortia and standardization working groups, e.g., [4],[5]. As there are ongoing test-site and test-bed developments for specific application scenarios, our objective is to capture the latest understanding in the development of those applications. In the future rigorous validation of specific systems can refine and tune these parameters.

The first eight applications in TABLE III enhance transportation safety, they are mostly *ad hoc based*, have relatively *stringent time requirements*, and they are given *high priority* at the data link. Practically all of them rely on cooperative awareness beaconing at high beacon rates: 10 beacons per second or message period of 100 ms. Among them, *Pre-Crash Sensing* has the most stringent latency requirements. It is noteworthy that, for the time being, such latency figures are not tied to specific reliability levels. In fact, it is necessary to specify end-to-end delays, that is, for V2V-enabled safety applications, maximum V2V application layer delays. This would include all processing, at all layers and represent the delay after which the given event (vehicle detection, collision hazard, etc) is perceived by the receiving vehicle. For multi-hop communication, the corresponding definitions would be necessary. It is also possible to adapt such requirements depending on the surrounding conditions.

From a different point of view, Pre-Crash Sensing is relevant for a small communication range (which corresponds to small distances between vehicles). Overall, the recommended ranges for each application can be beneficial to the protocol designer in many ways, for example, in terms of handling incoming messaging such as beacons.

Some of the transportation safety applications have relatively demanding positioning requirements: *Lane Change Warning* requires relative positioning accuracy of less than 2 m, whereas *Cooperative Forward Collision Warning* necessitates relative positioning accuracy of less than 1 m. The *Crash Avoidance Metrics Partnership* (CAMP) *Intersection Collision Avoidance* system, with two experimental intersections already deployed, requires

relative positioning accuracy of less than 0.5 m. All vehicles and RSUs are to be location-aware, but GNSS-based or other localization schemes provide a coarser-grained level of accuracy than the above-mentioned requirements. As a result, additional on-board processing is necessary.

The next four applications (9-12 in TABLE III) are related to transportation efficiency, enabled by ad hoc communication with the infrastructure (RSUs, generic or specialized such as the toll collection units). The assigned priority is lower than that of safety applications, beaconing rates are five to ten times lower, and the required latencies are up to five times higher. The communication is based on V2V protocols too. But a distinctive feature, compared to safety applications that rely on broadcast, is that there is unicast V2V communication; in some cases, cellular communication could be involved.

The final four applications (13-16) offer services to the users (passengers and drivers); they rely mostly on infrastructure-based communication rather than V2V data exchange, and mandate Internet access. In other words, the vehicle has to be an IP addressable host, and the corresponding servers be on-line and accessible either in an ad hoc V2I manner (when the vehicle is within range of an access point) or via cellular or other networks. Latency requirements are among the lowest, and cooperative awareness becomes secondary if not irrelevant. Nevertheless, other issues that are not VC-specific arise, such as Digital Rights Management (that is, mechanisms and policies that specify and enforce access control to the obtained content).

From the above discussion, we see a relation between communication and networking protocols and applications. Nonetheless, this is a joint development effort and thus there are still aspects to be defined and fine-tuned. Several projects take for granted that there will be V2V and V2I communication in the future, including the forms discussed in the previous sections. They consider an open VC architecture that makes data exchange possible, but they do not necessarily rely yet on advanced data exchange. This agnostic approach is interesting in the sense that one could develop an application without or with little VC now. In this vain, the *Highly Automated VEHicles for Intelligent Transport* (HAVE-IT) anticipates the availability of VC. The project develops a co-pilot that optimizes the task repartition between driver and co-driving system; with a redundant and fail-safe electronic architecture. The perception is currently local, but HAVE-IT prepares an architecture for cooperative data fusion in the future.

VII. FUTURE OUTLOOK

The surveyed recent concerted efforts have yielded significant results and momentum for further developments. In this article, we provide a concise survey of the state-of-

the-art, capturing qualitatively and quantitatively the technical approaches under development.

Nonetheless, several challenges lie ahead, before VC systems can be deployed. Continuing field tests, as those undertaken by projects such as SAFESPOT and VSC-A, is paramount. Building large-scale field experimentation is further necessary for thorough testing and validation of the system dependability. This includes not only the data link and networking technologies but also the applications themselves, notably those with the most stringent requirements. Ensuring efficient and effective operation even in challenging situations, even if unlikely to occur in practice, is necessary; for example, as the size of the VC networks scales up.

Meanwhile, the integration of strong and efficient security mechanisms should not be neglected, especially as an architecture and protocols for secure VC along with privacy enhancing technologies are developed [6]. With the appropriate design, secure VC systems can be as effective as non-secure ones. Thus, with the current and growing awareness on the importance of security, trustworthy VC systems could be deployed.

Additional aspects to consider include financial, legal, and organizational issues. For example, what will be the cost of deployment, and how will it be covered? Will the deployment leverage on existing systems and user-portable devices, such as smart phones? What will be first set of applications that will be deployed? How will authorities and services be instantiated in a heterogeneous environment that is subject to legislation that is not necessarily or even far from being harmonized?

Innovation is necessary, of course, in terms of market introduction. Without a large penetration of the solution (on vehicles and/or along the infrastructure), benefits for the final user (the driver) will be very limited. No one would agree to pay for something that will be useful only at some time in the future. It is crucial to understand how VC can be realistically deployed. Responsibilities, legal implications, and liabilities issues should be clearly specified.

Another essential step towards deployment is standardization: with contributions from projects, industrial consortia, and standardization committees and working groups.

In the future, solutions departing significantly from the current paradigm could emerge. Advanced Driver Assistance Systems (ADAS) and new sensing technologies can be highly beneficial, along with a large body of work on automated vehicles. Eventually, the most advanced Cooperative Systems would probably be fully automated, as per, for example, the CyberCars and CityMobil projects and the DARPA Challenge (<http://www.darpa.mil>) for

autonomous ground vehicles. Of course, very high levels of confidence would be necessary to gain broad user acceptance for vehicular communication systems, which could benefit personal and commercial mobility, contributing to their sustainability.
